We prospectively evaluated the prevalence, risk factors, and outcome after treatment of postoperative heterotopic ossification (HO) in a consecutive series of 210 total knee arthroplasties (TKAs) performed in 192 patients. We defined HO as the formation of mature lamellar bone at any site other than the central articulating surface. The overall prevalence was 46% (95% confidence interval, 41%-51%). Radiographic criteria for HO were identified by 2 observers in 47 joints on radiographs taken within 2 years after TKA. The observed prevalence of HO was 33% (95% confidence interval, 26%-39%) and 53% (95% confidence interval, 43%-62%) when observers were blinded to radiographic and clinical data, respectively. The overall and severe HO (grade 3 or 4) rates were correlated with body mass index, duration of the disease, sex, and alcohol consumption, whereas age, osteoarthritis, and the use of intra-articular steroid injections were not associated with HO. After TKA, severe HO was associated with restricted mobility, high rates of pain, and increased use of analgesics. After a mean follow-up of 5.9 years, the overall prevalence of HO was 37% (95% confidence interval, 32%-43%). TKA reduced the rate of HO but did not eliminate it. Prospective randomized studies with longer follow-up are needed to confirm the durability of TKA. We are delighted to announce the first version of emacs-live, the ability to edit C/C++ code in emacs. In addition to support for standard emacs editing capabilities, it features semantic highlighting of errors, cross-referencing, live preview and editing, and an integrated debugger. You can find out more about it from the following 82157476af
